**Project Structure:**

The project structure follows the standard Django app structure with key components as follows:

- Authentication: Manages user registration, login, and authentication using the built-in authentication system and custom authentication backend.
- Document: Contains models for Document, custom permission classes, serializers, and views related to document management, upload, conversion, and retrieval.
- User: Handles the custom user model, serializers, and views for user registration and profile updates.
- Settings: Stores Django project settings, including authentication backends, REST framework settings, and other configurations.
- Static and Media: Manages static files and user-uploaded documents.

**Reason:** I have created folders named views and urls; then stored all the views and urls files in the related folder. In this way, each application files remain more structured and easy to find out files.
